Graph representation

Given graph G = (V, E).

- May be either directed or undirected.
- Two common ways to represent for algorithms:
 - 1. Adjacency lists.
 - 2. Adjacency matrix.

When expressing the running time of an algorithm, it's often in terms of both |V| and |E|.

In asymptotic notation - and *only* in asymptotic notation - we'll drop the cardinality.

Example: O(V+E).

Adjacency lists

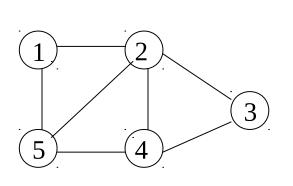

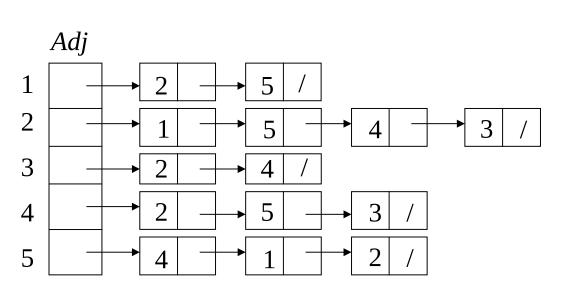

Array Adj of |V| lists, one per vertex.

Vertex *u*'s list has all vertices *v* such that $(u, v) \in E$.

(Works for both directed and undirected graphs.)

Example: For an undirected graph:

Adjacency lists

If edges have weights, can put the weights in the lists.

Weight: $w: E \rightarrow \mathbf{R}$

Space: $\Theta(V+E)$

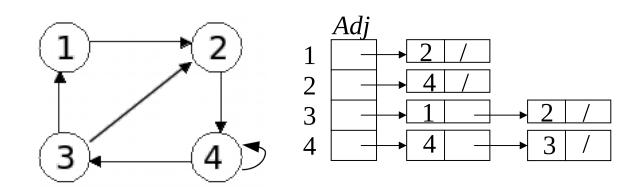

Time: to list all vertices adjacent to u: $\Theta(\text{degree}(u))$

Time: to determine if $(u, v) \in E$: O(degree(u))

Example: For a directed graph:

Same asymptotic space and time

Adjacency matrix

$$|V| \times |V|$$
 matrix $A = (a_{ij})$

$$a_{ij} = \begin{cases} 1 & \text{if } (i,j) \in E \\ 0 & \text{otherwise} \end{cases}$$

$$|V| \times |V| \text{ matrix } A = (a_{ij})$$

$$a_{ij} = \begin{cases} 1 & \text{if } (i,j) \in E \\ 0 & \text{otherwise} \end{cases}$$

$$1 & 2 & 3 & 4 & 5 \\ 1 & 0 & 1 & 0 & 0 & 1 \\ 2 & 1 & 0 & 1 & 1 & 1 \\ 3 & 0 & 1 & 0 & 1 & 0 \\ 4 & 0 & 1 & 1 & 0 & 1 \\ 5 & 1 & 1 & 0 & 1 & 0 \end{cases}$$

Space: $\Theta(V^2)$

Time: to list all vertices adjacent to $u: \Theta(V)$

Time: to determine if $(u, v) \in E$: $\Theta(1)$

Can store weights instead of bits for weighted graph

Breadth-first search

Input: Graph G = (V,E), either directed or undirected, and **source vertex** $s \in V$

Output: d[v] = distance (smallest # of edges) from s to v, for all $v \in V$

Also $\pi[v] = u$ such that (u, v) is last edge on a shortest path $s \to v$

- *u* is *v*'s *predecessor*
- set of edges $\{(\pi[v], v) : v \neq s\}$ forms a tree

Breadth-first search

Idea: Send a wave out from *s*.

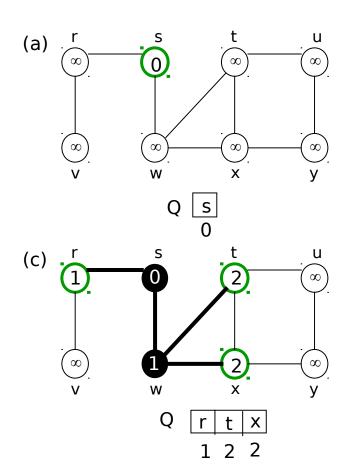

- First hits all vertices 1 edge from *s*.
- From there, hits all vertices 2 edges from *s*.
- Etc.

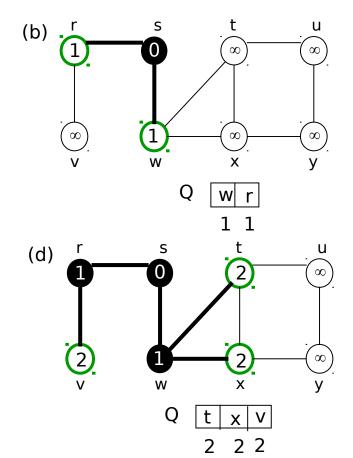

Use FIFO queue *Q* to maintain wavefront.

• $v \in Q$ if and only if wave has hit v but has not come out of v yet.

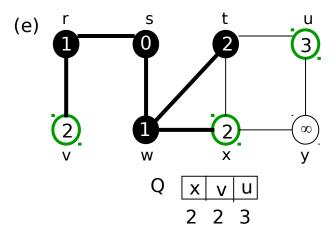

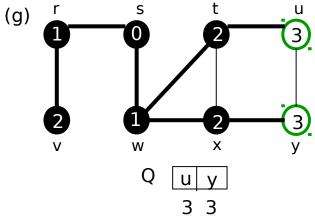

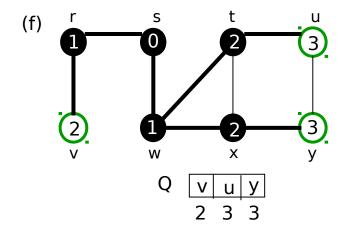

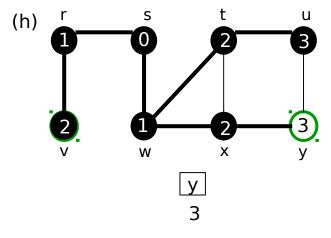

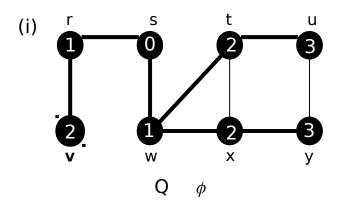

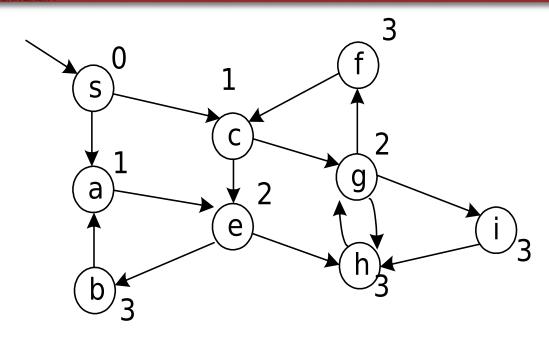

```
BFS(V, E, s)
for each u \in V - \{s\}
    do d[u] \leftarrow \infty
d[s] \leftarrow 0
Q \leftarrow \varphi
ENQUEUE(Q, s)
While Q \neq \varphi
  do u \leftarrow DEQUEUE(Q)
     for each v \in Adj[u]
            do if d[v] = \infty
                  then d[v] \leftarrow d[u] + 1
                       ENQUEUE(Q, v)
```

Example: directed graph

Can show that *Q* consists of vertices with *d* values.

$$i$$
 i i i $i+1$ $i+1$ $i+1$ $i+1$

- Only 1 or 2 values.
- If 2, differ by 1 and all smallest are first.

Since each vertex gets a finite *d* value at most once, values assigned to vertices are monotonically increasing over time.

BFS may not reach all vertices.

Time = O(V + E).

- O(V) because every vertex enqueued at most once.
- O(E) because every vertex dequeued at most once and we examine (u, v) only when u is dequeued. Therefore, every edge examined at most once if directed, at most twice if undirected.

Depth-first search

Input: G = (V, E), directed or undirected. No source vertex given!

Output: 2 *timestamps* on each vertex:

 $\triangleright d[v] =$ discovery time

 $\triangleright f[v] =$ finishing time

These will be useful for other algorithms later on.

Can also compute $\pi[v]$.

Will methodically explore every edge.

Start over from different vertices as necessary.

As soon as we discover a vertex, explore from it.

▶ Unlike BFS, which puts a vertex on a queue so that we explore from it later.

As DFS progresses, every vertex has a *color*:

- ► WHITE = undiscovered
- GRAY = discovered, but not finished (not done exploring from it)
- BLACK = finished (have found everything reachable from it)

Discovery and finish times:

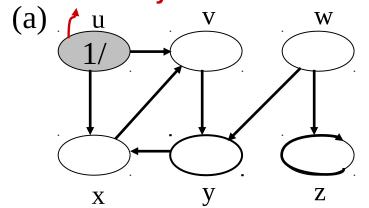

- ▶ Unique integers from 1 to 2|V|.
- For all v, d[v] < f[v].

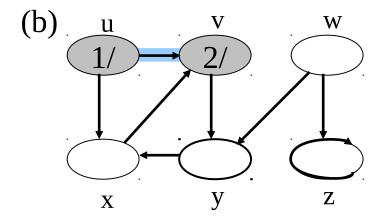

In other words, $1 \le d[v] \le f[v] \le 2|V|$.

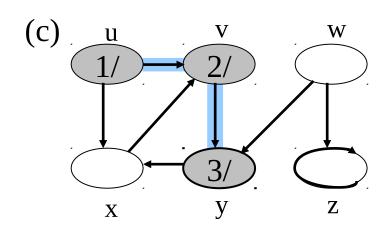

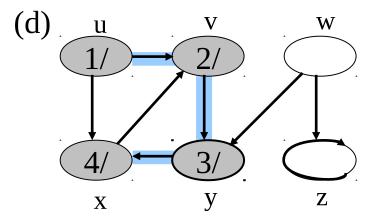

Discovery time

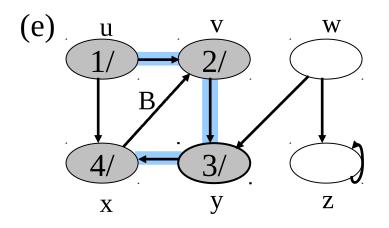

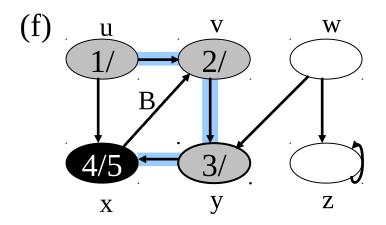

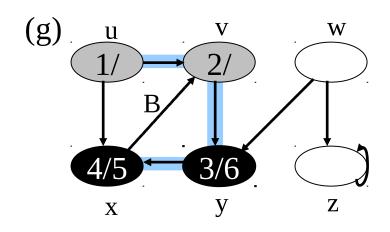

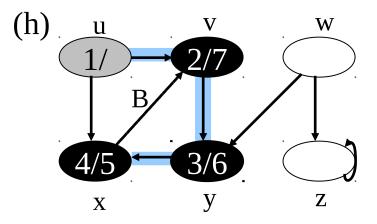

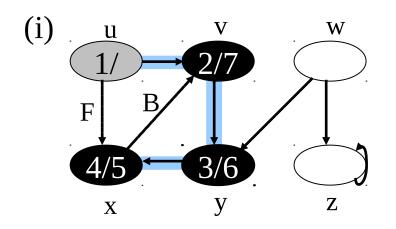

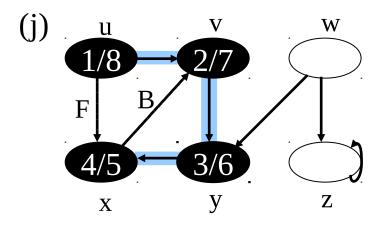

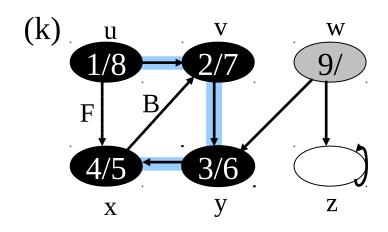

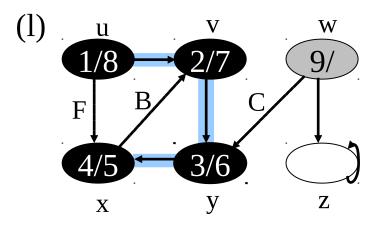

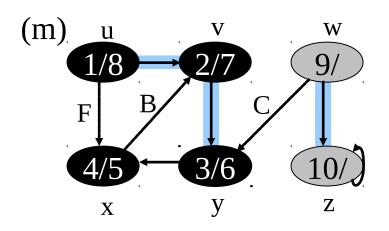

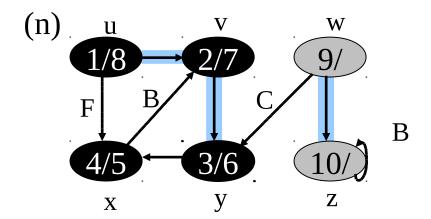

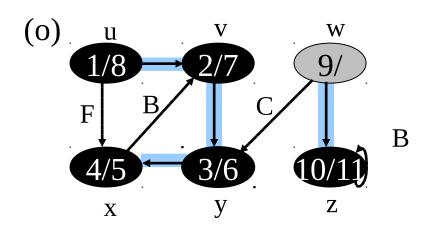

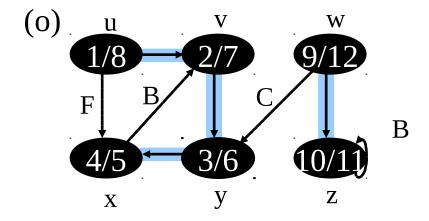

```
Pseudocode: Uses a global timestamp time. DFS(V,E) for each u \in V do color[u] \leftarrow WHITE time \leftarrow 0 for each u \in V do if color[u] = WHITE then DFS - Visit(u)
```

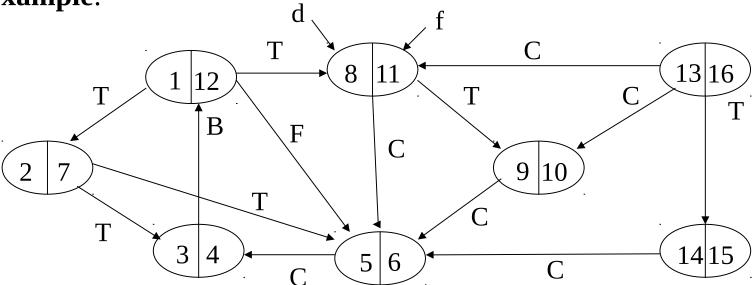

```
DFS - Visit(u)
color[u] \leftarrow GRAY
                                 \Box discover u
time \leftarrow time + 1
d[u] \leftarrow time
for each v \in Adj[u] \square explore (u, v)
   do if color[v] = WHITE
         then DFS - Visit(v)
color[u] \leftarrow BLACK
time \leftarrow time +1
                                  \Box finish u
f[u] \leftarrow time
```

Example:

Time = $\Theta(V + E)$.

- Similar to BFS analysis.
- Θ , not just O, since guaranteed to examine every vertex and edge.

DFS forms a *depth-first forest* comprised of ≥ 1 *depth-first trees*.

Each tree is made of edges (u, v) such that u is gray and v is white when (u, v) is explored.

Theorem (Parenthesis theorem)

[Proof omitted.]

For all u, v, exactly one of the following holds:

- 1. d[u] < f[u] < d[v] < f[v] or d[v] < f[v] < d[u] < f[u] and neither of u and v is a descendant of the other.
- 2. d[u] < d[v] < f[v] < f[u] and v is a descendant of u.
- 3. d[v] < d[u] < f[u] < f[v] and u is a descendant of v.

So d[u] < d[v] < f[u] < f[v] cannot happen.

Like parentheses:

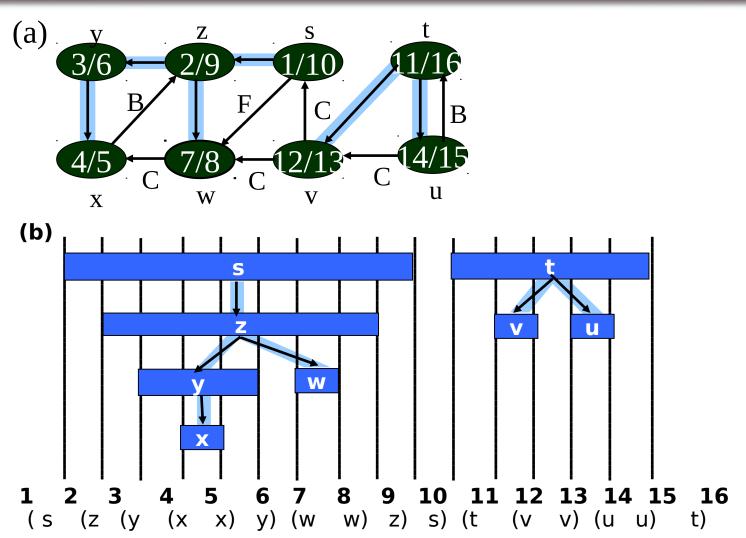

- OK: ()[] ([]) [()]
- Not OK: ([)] [(])

Corollary

v is a proper descendant of u if and only if d[u] < d[v] < f[v] < f[u].

Theorem (White-path theorem)

[Proof omitted.]

v is a descendant of u if and only if at time d[u], there is a path $u \rightarrow v$ consisting of only white vertices. (Except for u, which was *just* colored gray.)

Classification of edges

- ► **Tree edge:** in the depth-first forest.
 - Found by exploring (u, v).
- **Back edge:** (u, v), where u is a descendant of v.
- ▶ *Forward edge*: (*u*, *v*), where *v* is a descendant of *u*, but not a tree edge.
- Cross edge: any other edge. Can go between vertices in the same depth-first tree or in different depth-first trees.

In an undirected graph, there may be some ambiguity since (u, v) and (v, u) are the same edge. Classify by the first type above that matches.

Theorem [Proof omitted.]

In DFS of an undirected graph, we get only tree and back edges. No forward or cross edges.

Topological sort

Directed acyclic graph (dag)

A directed graph with no cycles.

Good for modeling processes and structures that have a

partial order:

- ightharpoonup a > b and $b > c \Rightarrow a > c$.
- ▶ But may have a and b such that neither a > b nor b > a.

Can always make a *total order*

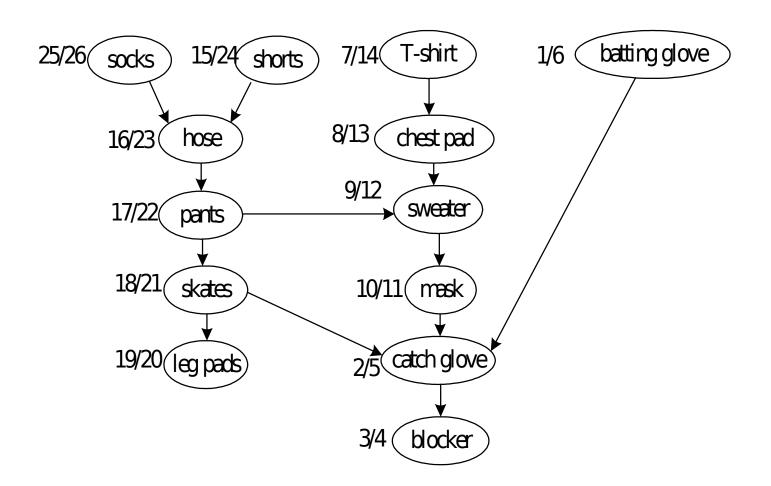

(either a > b or b > a for all $a \neq b$) from

a partial order. In fact, that's what a topological sort will do.

Example: dag of dependencies for putting on goalie equipment:

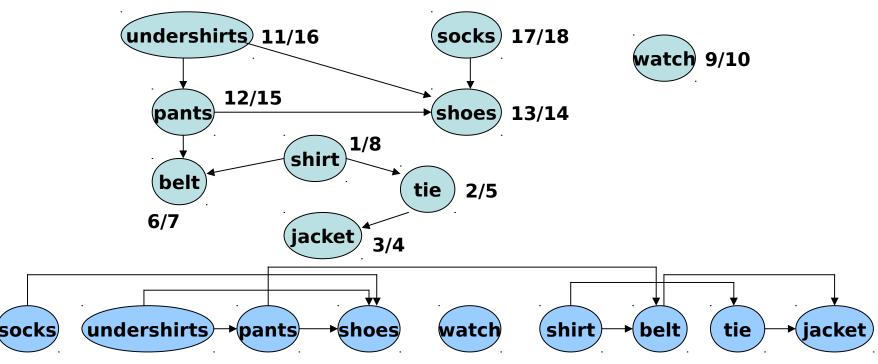

Topological sort

▷ 定義:

A topological sort of a dag G=(V, E) is a linear ordering of all its vertices. (dag: Directed acyclic graph) \square edge(u, v), u appears before v in the ordering

Lemma

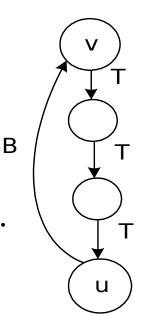

A directed graph *G* is acyclic if and only if a DFS of *G* yields no back edges.

Proof (\Rightarrow): Show that back edge \Rightarrow cycle.

Suppose there is a back edge (u, v).

Then v is ancestor of u in depth-first forest.

Therefore, there is a path $v \rightarrow u$, so $v \rightarrow u \rightarrow v$ is a cycle.

(⇐):

Show that cycle \Rightarrow back edge.

Suppose *G* contains cycle *c*.

At time d[v], vertices of c form a white path $v \rightarrow u$ (since v is the first vertex discovered in c).

By white-path theorem, u is descendant of v in depth-first forest.

Therefore, (u, v) is a back edge.

Topological sort of a dag: a linear ordering of vertices such that if $(u, v) \in E$, then u appears somewhere before v. (Not like sorting numbers.)

TOPOLOGICAL-SORT(V, E) call DFS(V, E) to compute finishing times f[v] for all $v \in V$ output vertices in order of *decreasing* finish times

Don't need to sort by finish times.

- Can just output vertices as they're finished and understand that we want the *reverse* of this list.
- Or put them onto the *front* of a linked list as they're finished.
 When done, the list contains vertices in topological sorted order.

Time: $\Theta(V+E)$

Order:

- 26 socks
- 27 shorts
- 28 hose
- 29 pants
- 21 skates
- 20 leg pads
- 14 t-shirt
- 13 chest pad
- 12 sweater
- 11 mask
- 6 batting glove
- 5 catch glove
- 4 blocker

Correctness: Just need show if $(u, v) \in E$, then f[v] < f[u]. When we explore (u, v), what are the colors of u and v?

- \triangleright *u* is gray.
- ► Is *v* gray, too?
 - No, because then *v* would be ancestor of *u*.
 - \Rightarrow (*u*, *v*) is a back edge.
 - ⇒ contradiction of previous lemma (dag has no back edges).

- Is *v* white?
 - Then becomes descendant of *u*.

By parenthesis theorem, d[u] < d[v] < f[v] < f[u].

- Is *v* black?
 - Then *v* is already finished.

Since we're exploring (u, v), we have not yet finished u.

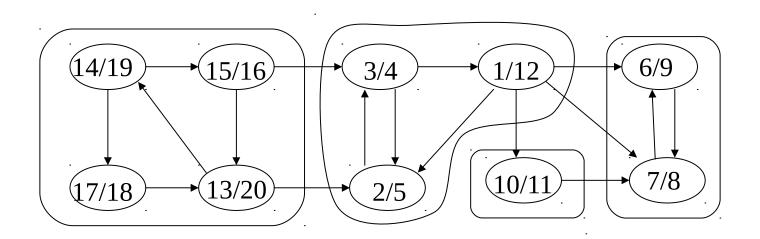

Therefore, f[v] < f[u].

Strongly connected components

Given directed graph G = (V,E).

A *strongly connected component (SCC)* of G is a maximal set of vertices $C \subseteq V$ such that for all $u, v \in C$, both $u \rightarrow v$ and $v \rightarrow u$.

Example: [Just show SCC's at first. Do DFS a little later.]

Algorithm uses G^T = **transpose** of G.

- $ightharpoonup G^{T} = (V, E^{T}), E^{T} = \{(u, v) : (v, u) \in E\}.$
- $ightharpoonup G^{T}$ is G with all edges reversed.

Can create G^T in $\Theta(V + E)$ time if using adjacency lists.

Observation: G and G^T have the same SCC's. (u and v are reachable from each other in G if and only if reachable from each other in G^T .)

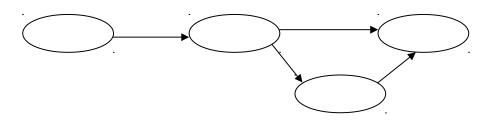

Component graph

- GSCC = (VSCC, ESCC).
- $ightharpoonup V_{SCC}$ has one vertex for each SCC in G.
- \triangleright E^{SCC} has an edge if there's an edge between the corresponding SCC's in G.

For our example:

Lemma

Gscc is a dag. More formally, let C and C' be distinct SCC's in G, let $u, v \in C, u', v' \in C$ ', and suppose there is a path $u \to u$ ' in G. Then there cannot also be a path $v' \to v$ in G.

Proof Suppose there is a path $v' \rightarrow v$ in G. Then there are paths $u \rightarrow u' \rightarrow v'$ and $v' \rightarrow v \rightarrow u$ in G. Therefore, u and v' are reachable from each other, so they are not in separate SCC's.

SCC(G)

call DFS(G) to compute finishing times f[u] for all u

compute G^{T}

call DFS(G^T), but in the main loop, consider vertices in order of decreasing f[u]

(as computed in first DFS)

output the vertices in each tree of the depth-first forest formed in second DFS

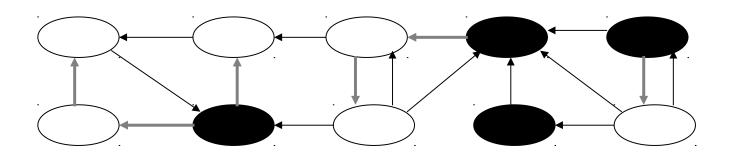

as a separate SCC

Example:

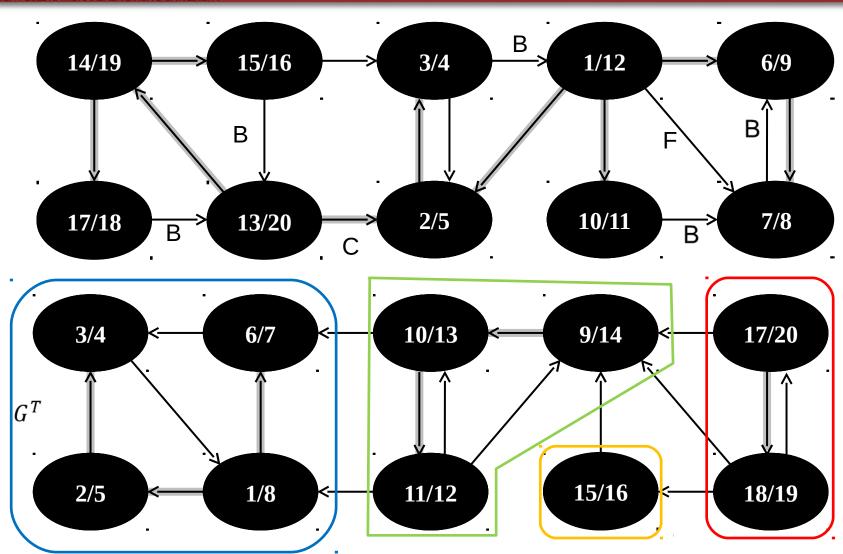

- 1. Do DFS
- 2. G^{T}
- 3. DFS (roots blackened)

Time: $\Theta(V + E)$.

How can this possibly work?

Idea: By considering vertices in second DFS in decreasing order of finishing times from first DFS, we are visiting vertices of the component graph in topological sort order.

To prove that it works, first deal with 2 notational issues:

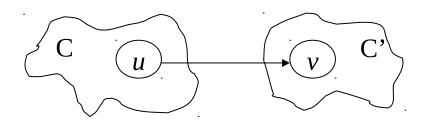

- ▶ Will be discussing d[u] and f[u]. These always refer to first DFS.
- ightharpoonup Extend notation for d and f to sets of vertices U V:
 - \triangleright $d(U) = \min_{u \in U} \{d[u]\}$ (earliest discovery time)
 - $f(U) = \max_{u \in U} \{f[u]\} \text{ (latest finishing time)}$

Lemma

Let *C* and *C*' be distinct SCC's in G = (V, E). Suppose there is an edge $(u, v) \in E$ such that $u \in C$ and $v \in C$ '.

Then f(C) > f(C').

Proof

Two cases, depending on which SCC had the first discovered vertex during first DFS.

▶ If d(C) < d(C'), let x be the first vertex discovered in C. At time d[x], all vertices in C and C' are white. Thus, there exist paths of white vertices from x to all vertices in C and C'.

By the white-path theorem, all vertices in *C* and *C*' are descendants of *x* in depth-first tree.

By the parenthesis theorem, f[x] = f(C) > f(C').

▶ If d(C) > d(C'), let y be the first vertex discovered in C'. At time d[y], all vertices in C' are white and there is a white path from y to each vertex in $C' \Rightarrow$ all vertices in C' become descendants of y.

Again, f[y] = f(C').

At time d[y], all vertices in C are white.

By earlier lemma, since there is an edge (u, v), we cannot have a path from C' to C.

So no vertex in *C* is reachable from *y*.

Therefore, at time f[y], all vertices in C are still white.

Therefore, for all $w \in C$, f[w] > f[y], which implies that f(C) > f(C').

Corollary

Let C and C' be distinct SCC's in G = (V, E). Suppose there is an edge $(u, v) \in E^T$, where $u \in C$ and $v \in C$ '. Then f(C) < f(C').

Proof $(u, v) \in E^{T} \Rightarrow (v, u) \in E$. Since SCC's of G and G^{T} are the same, f(C') > f(C).

Corollary

Let C and C' be distinct SCC's in G = (V, E), and suppose that f(C) > f(C').

Then there cannot be an edge from C to C' in G^T .

Proof It's the contrapositive of the previous corollary.

Why the SCC procedure works:

- When we do the second DFS, on G^T , start with SCC C such that f(C) is maximum.
 - The second DFS starts from some $x \in C$, and it visits all vertices in C.
 - Corollary says that since f(C) > f(C') for all $C' \neq C$, there are no edges from C to C' in G^T .

Therefore, DFS will visit *only* vertices in *C*.

- □ The next root chosen in the second DFS is in SCC C' such that f(C) is maximum over all SCC's other than C. DFS visits all vertices in C', but the only edges out of C' go to C, which we've already visited.
- ☐ Each time we choose a root for the second DFS, it can reach only
- vertices in its SCC—get tree edges to these,
- vertices in SCC's already visited in second DFS—get no tree edges to these.

We are visiting vertices of $(G^T)^{SCC}$ in reverse of topologically sorted order.
